#### Abstract

Various acoustic parameters such as isentropic compressibility ( $\beta s$ ), intermolecular free length ( $L f$ ), apparent molar volume ( $\Phi v$ ), apparent molar compressibility ( $\Phi k$ ), molar compressibility ( $W$ ), molar sound velocity $(R)$, acoustic impedance $(\mathrm{Z})$ of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in $10 \%, 20 \%$ and $30 \%$ Dioxane + Water at 303.15 K have been determined from ultrasonic velocity ( $U$ ), density ( $\rho$ ) and relative viscosity ( $\eta r$ ) of the solution. These parameters are related with the molar concentration of the solution and reflects the distortion of the structure of the solvent i.e. Dioxane + Water.

Keywords: Ultrasonic velocity, acoustic parameter, density, relative viscosity, Dioxane + water.

## 1. Introduction

The ultrasonic studies find extensive applications as sound speed in liquids and liquid mixtures is intrinsically related with many parameters which characterize the physico chemical behaviour of the liquids and liquid systems. Mixed solvents rather than single pure liquids are of utmost practical importance in most of the chemical and industrial processes as they provide a wide range mixture of two or more components in varying proportions so as to permit continuous adjustment of the derived properties of the medium. Intermolecular interactions in various binary liquid mixtures at different temperatures have been studied by several authors (Bhoj et al. 2006, Nain et al. 2008, Thanuja et al. 2011, Zareena et al. 2013) Physico chemical properties like density, viscosity and speed of sound have got considerable importance in forming theoretical models as well as their applications in a number of branches of science. A considerable progress has been made theoretical understanding of liquid - liquid mixture (Anil et al. 2007, Shahla et al. 2009, Rajgopal et al. 2011). An attempt has been made to elucidate the ion-ion interaction between nitroprusside ions and ion-solvent interaction of sodium nitroprusside in aquo-organic mixtures at 308.15 K (Smrutiprava et al 2013).The binary mixture are indispensable for many chemical process industries e.g. petroleum, petrochemicals, where physico chemical processes are involved to handle the mixtures of hydrocarbons, alcohols, ketones etc. for accurate designing equipment it is necessary to know the interaction between the components of mixture. The thermodynamic studies of binary solutions have attracted much attention of scientists and experimental data on a number of systems are available from review and publications. Viscosity, density measurements and the properties derived from these are excellent tools to detect solute - solute and solvent interactions. It is used in different fields of scientific researches in physics, chemistry, biology, medicines and industries. The present work deals with the measurement of density ( $\rho$ ), relative viscosity $\left(\eta_{\mathrm{r}}\right)$, apparent molar volume $\left(\Phi_{\mathrm{v}}\right)$, ultrasonic velocity $(\mathrm{U})$ and the derived acoustical parameters with Dioxane + Water mixture at 303.15 K using $\mathrm{Cd}\left(\mathrm{NO}_{3}\right) \cdot 2 \mathrm{H}_{2} \mathrm{O}$ as electrolyte.

## 2. Materials and Method

The solute Cadmium nitrate, $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (E-Merck) used is of high purity and found up to the standard. The solvents used were purified by appropriate method. Dioxane (E-Merck) and water were triple distilled. Purity was about $99.9 \%$ which was in good agreement with the standard values of density, viscosity etc. the solvents of different Dioxane contents were prepared by taking required volume of Dioxane in distilled water. The densities of pure components and binary mixtures were measured using pre-calibrated pycnometer with an accuracy of $0.053 \%$ at
303.15 K . Viscosities of pure liquids and their mixtures were measured using Ostwald's Viscometer. The flow time of pure liquids and liquid mixtures were measured using an accurate stop watch with a precision of $\pm 0.15$. Ultrasonic velocity was measured by using single crystal Ultrasonic interferometer (Mittal Enterprise, Model F-81) operating at a frequency of 5 MHz . Water from a thermostatically regulated bath (Toshniwal, India) equipped with Jumo D.B.P. temperature sensor was circulated with a sample holder (with double wall) to maintain the temperature of the liquid constant at 303.15 K with a precision of 0.01 K .

## 3. RESULTS AND DISCUSSION

The apparent molar volume ( $\Phi$ ) was determined from the following:
$\phi=\frac{M}{\rho_{0}}-\frac{\left[\rho_{0}-\rho_{0}\right]}{\rho_{0}} \times \frac{1000}{C}$
and the results are noted in (Table 1) where:
$\mathrm{M}=$ molecular mass of the solute
$\rho_{0}=$ Density of the solvent
$\rho=$ density of the solution
$\mathbf{C}=$ Molar concentration of the solution. The data obtained follow Masson's equation (Masson 1929) $\left(\phi=\phi_{0}+S_{v} \sqrt{\mathrm{C}}\right)$ (Plot of $\phi$ vs. $\sqrt{\mathrm{C}}$ is linear).

The values of limiting apparent molar volume $\left(\phi_{0}\right)$ and slope $\left(S_{v}\right)$ calculated from the graph are recorded in Table 2. The positive value of $S_{\mathrm{v}}$ indicates ion - ion interaction. The increase of $\Phi_{0}$ with increasing concentration of Dioxane may be attributed due to low charge density.

The relative viscosity $\left(\eta_{\mathrm{r}}\right)$ values are determined from the following equation and recorded in (Table 1)

$$
\eta_{r}=\frac{\eta}{\eta_{0}}=\frac{t}{t_{0}} \times \frac{\rho}{\rho_{0}}
$$

Where $\eta_{\mathrm{r}}$ is relative viscosity and $\eta, \rho$ and $\mathrm{t}, \eta_{0}, \rho_{0}$ and $\mathrm{t}_{0}$ are the coefficient of viscosity, density and time of efflux of the solution and solvent respectively. The values so obtained show that the relative viscosity $\left(\eta_{r}\right)$ increases with the increase in concentration of Dioxane. This may be due to increase in the degree of hydrogen bonding between Dioxane and water. The relative viscosity increases with increase in concentration of the solute. This is in agreement with the work of Widemann et al. 1981

The plot of $\left(\frac{n_{r}-1}{\sqrt{C}}\right)$ vs. $\sqrt{C}$ is linear (Fig.1), which is in good agreement with the Jones -
Dole equation (Jone et al. 1929)
$\eta_{r}=1+\mathrm{A} \sqrt{\mathrm{C}}+\mathrm{BC}$

Table2. Limiting apparent molar volume $\left(\Phi_{0}\right)$, Limiting Slope $(\mathrm{Sv}), \mathrm{A}$ and B of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$ in Dioxane + Water at 303.15 K .

| Parameter | $\mathbf{1 0 \%}$ | $\mathbf{2 0 \%}$ | $\mathbf{3 0 \%}$ |
| :--- | :--- | :--- | :--- |
| $\Phi_{0}\left(\mathrm{~cm}^{3} \mathrm{~mol}^{-1}\right)$ | 100.6 | 105.8 | 110.5 |
| $\mathrm{~S}_{\mathrm{v}}\left(\mathrm{cm}^{9 / 2} \mathrm{~mol}^{-3 / 2}\right)$ | 6.70 | 6.72 | 6.79 |
| $\mathrm{~A} \times 10^{2}\left(\mathrm{~mol}^{-1 / 2} \mathrm{~L}^{1 / 2}\right)$ | 3.43 | 3.51 | 3.60 |
| $\mathrm{~B}\left(\mathrm{~mol}^{-1} \mathrm{~L}\right)$ | 0.691 | 0.752 | 0.894 |

The increasing value of A with Dioxane content supports the increase in electrostatic attraction as well as ion- solvent interactions while the increase in $S_{v}$ value attribute to large size of solvent molecules and strong association between water and organic solvent through hydrogen bonding.

The ultrasonic velocity (U) (Rajendran et al. 1996, Haribabu et al. 1996), isentropic compressibility ( $\beta_{\mathrm{s}}$ ) (Jacobson et al. 1985), molar compressibility (W), molar sound velocity (R), acoustic impedance (Z) (Nikam et al. 1990), intermolecular free length ( $\mathrm{L}_{\mathrm{f}}$ ) and apparent molar compressibility $\left(\Phi_{\mathrm{k}}\right)$ of $\mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in $10 \%, 20 \%$ and $30 \%$ Dioxane + water at 303.15 K are recorded in (Table 3) and (Fig. 2-7).

## 4. Conclusions

The data measured shows that the ultrasonic velocity increases with increase in concentration in all cases along with molar compressibility (W), molar sound velocity ( R ) while intermolecular free length ( $\mathrm{L}_{\mathrm{f}}$ ) and acoustic impedance ( Z ) decreases with increase in concentration. The increase in isentropic compressibility $\left(\beta_{\mathrm{s}}\right)$ with decreasing concentration suggest minimum interaction between the unlike molecules (i.e. solute \& solvent molecules). Acoustic impedance $(Z)$ decreases with decrease in concentration, which supports the possibility of weak interactions between unlike molecules and is also used for accessing the absorption of sound in a media. The increasing ultrasonic velocity ( U ) and molar compressibility ( W ) with increasing concentration represents the decrease in cohesive force which is responsible for the structure breaking nature of the solute. The hydrogen bond existing Dioxane and water is disrupted by the solute molecules and thereby formation of new bonding between solute and solvent molecules has occurred. As most of the solvent molecules are engaged in interaction with the solute, addition of more solute molecules to the solvent leads to the acceleration of the process of breaking of aggregates of solvent molecules. This process leads to the inhibition of propagation of sound waves due to large sized solute molecules acting as structure promoters. To conclude the formation of more cluster of the solute - solvent molecules with increase in hydro-dynamic volume increases the isothermal compressibility.

## ACKNOWLEDGEMENT

The authors are thankful to P.G. Department of Chemistry, Ravenshaw University, Cuttack, Odisha for providing all possible facilities to carry out this work.
